- The problem
- Presentation time
- Where is the time?
 - media element time, document time, rendered time, runtime
- Runtime
 - linking within/among multimedia presentations

What is the problem?

How can we combine timing and linking in multimedia?

Author:

- chronological development of the narrative
- temporal arrangement of media elements

Hypertext system designer:

- add concurrent media streams to document
- include temporal aspects in model

Multimedia system designer:

- add links to linear multimedia presentation

Three cases

- timeline of single linear multimedia presentation
- navigation among linear multimedia presentations
- navigation within and among non-linear multimedia presentations

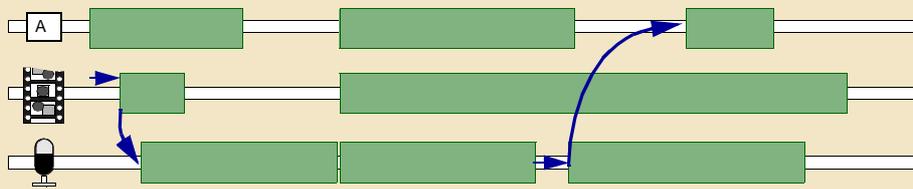

Document vs. presentation time

document—underlying storage representation perceived by an author

presentation—perceived by a reader

Document needs to contain information for directing playback

- which elements
- when displayed
- for how long
- when removed

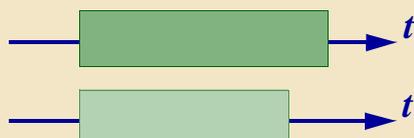

Presentation time

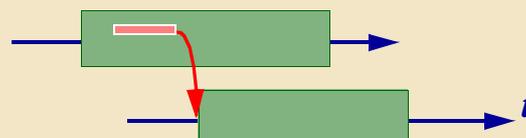

Media element time

Document time

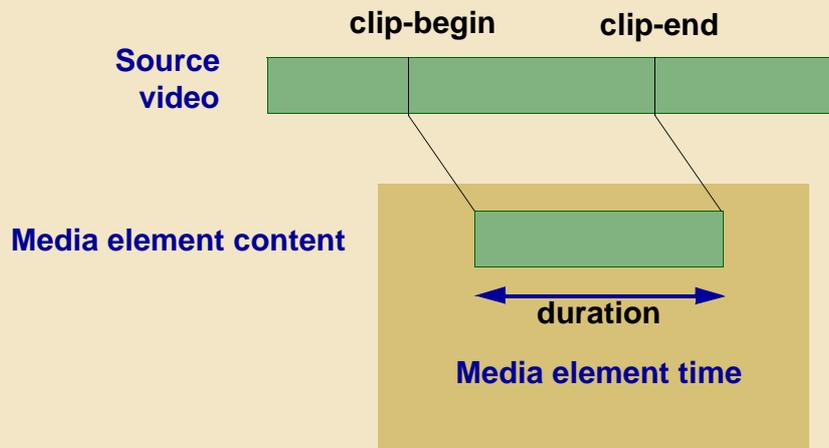

Rendered time

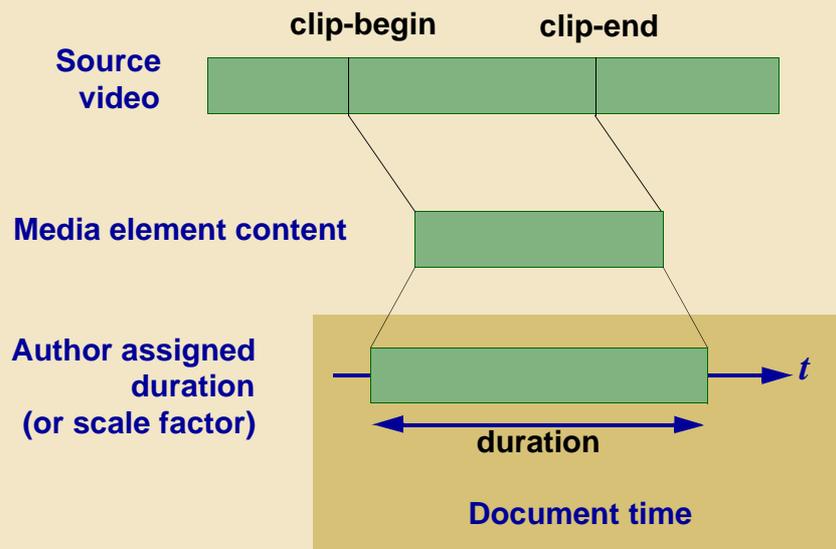

Runtime

Media element time

SMIL **clip-begin** and **clip-end**

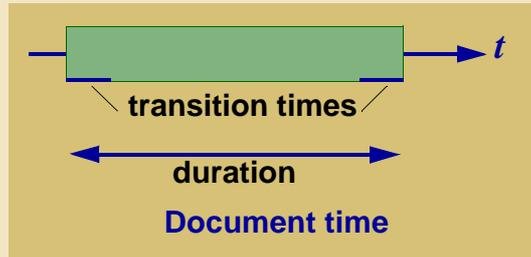

Document time

SMIL **repeat** and **duration**

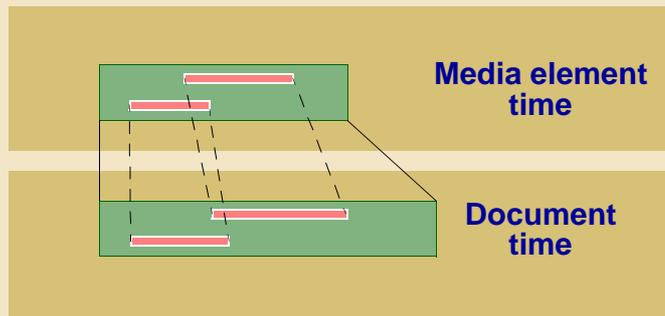

Transition time and anchor time

Author assigned duration
(or scale factor)

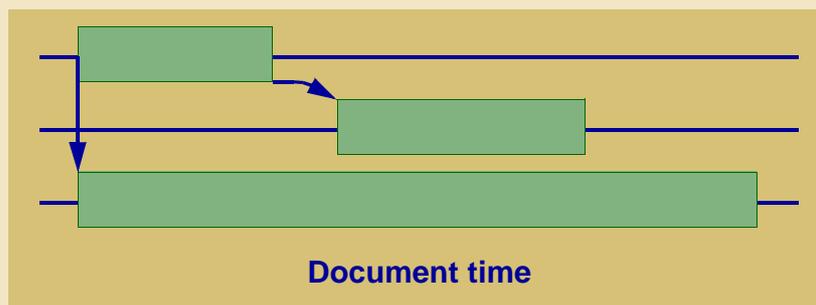

Anchors defined in content

Anchor durations

Temporal composition

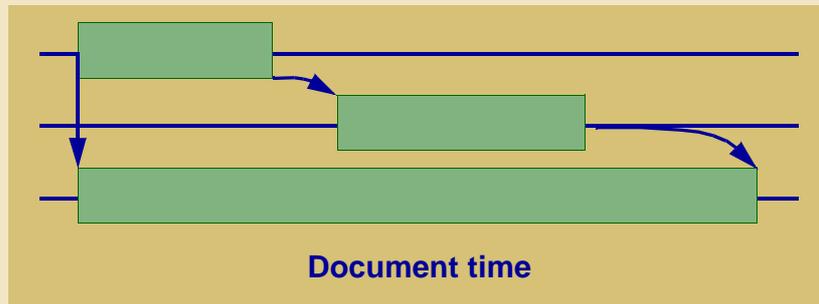

SMIL *par*, *seq*, *begin*, and *end*

Par and *seq* have implicitly defined synchronization constraints

Par and *seq* can also have *duration* and *repeat* attributes

Soft vs. hard synchronization

Multiple synchronization arcs

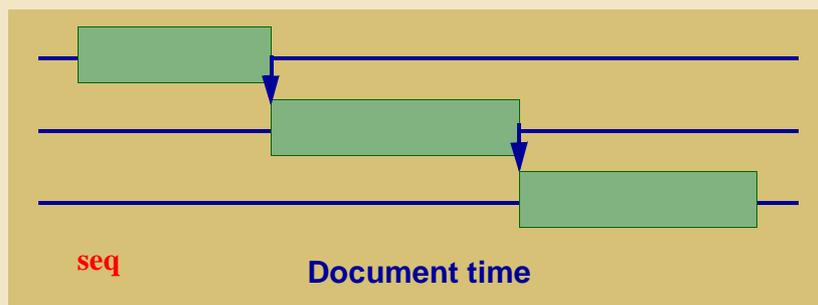

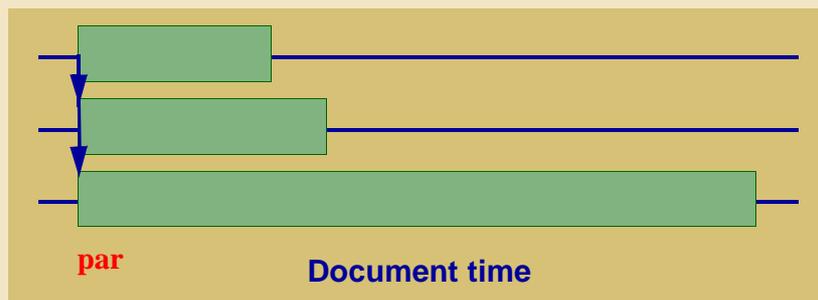

Second arc constrains indefinite duration of lowest component or scales intrinsic duration.

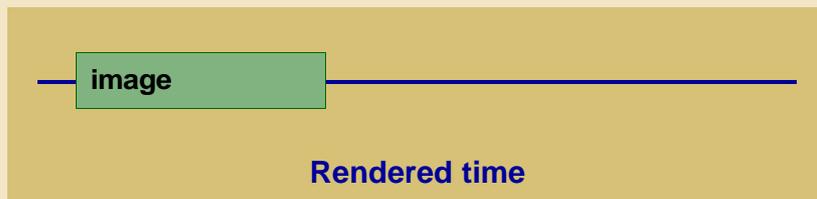

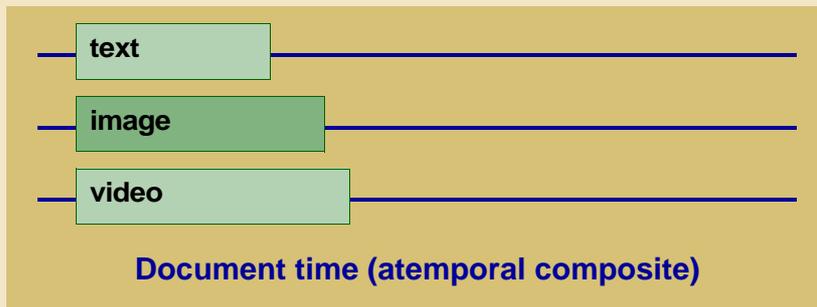

Further sync arcs are invalid.

More complex model could allow different tempos within component.

Implicit synchronization arcs

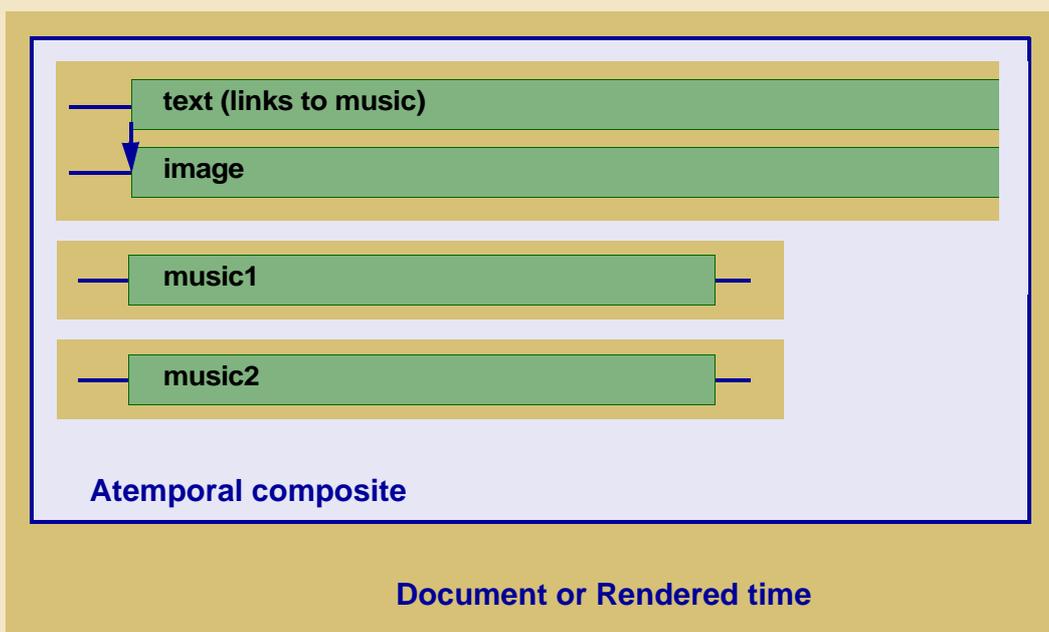

Rendered time

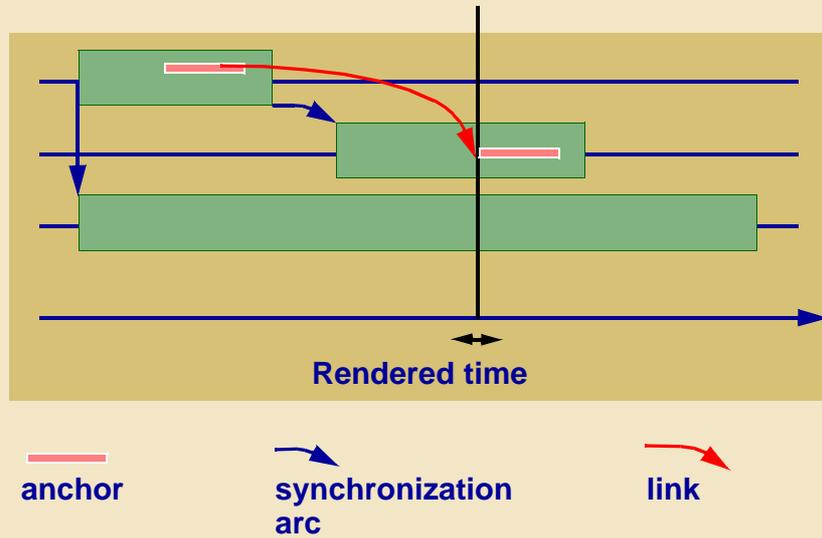

SMIL switch

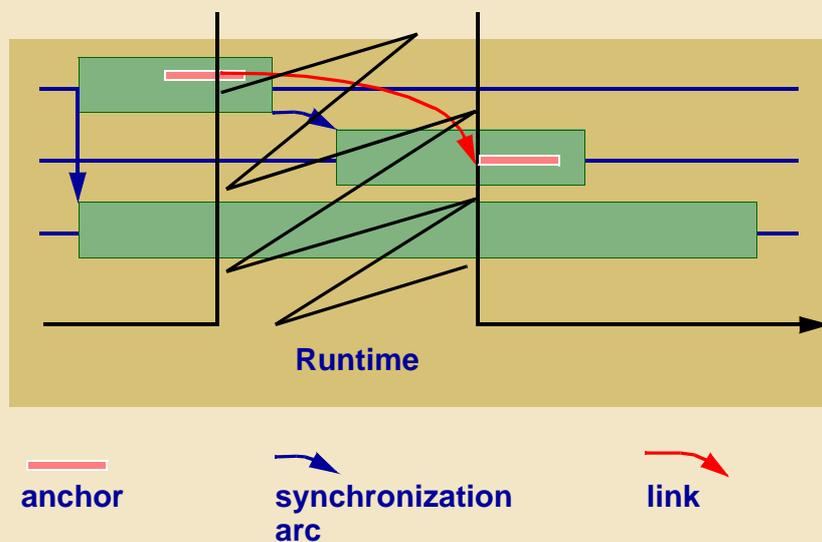

Atemporal Composition

Interaction within a linear multimedia presentation

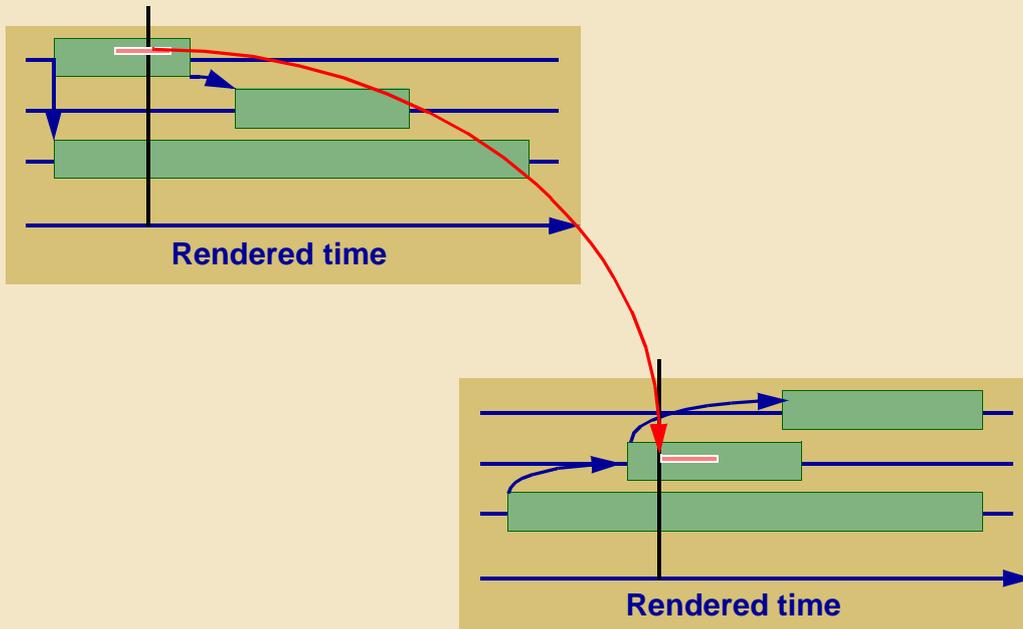

Runtime

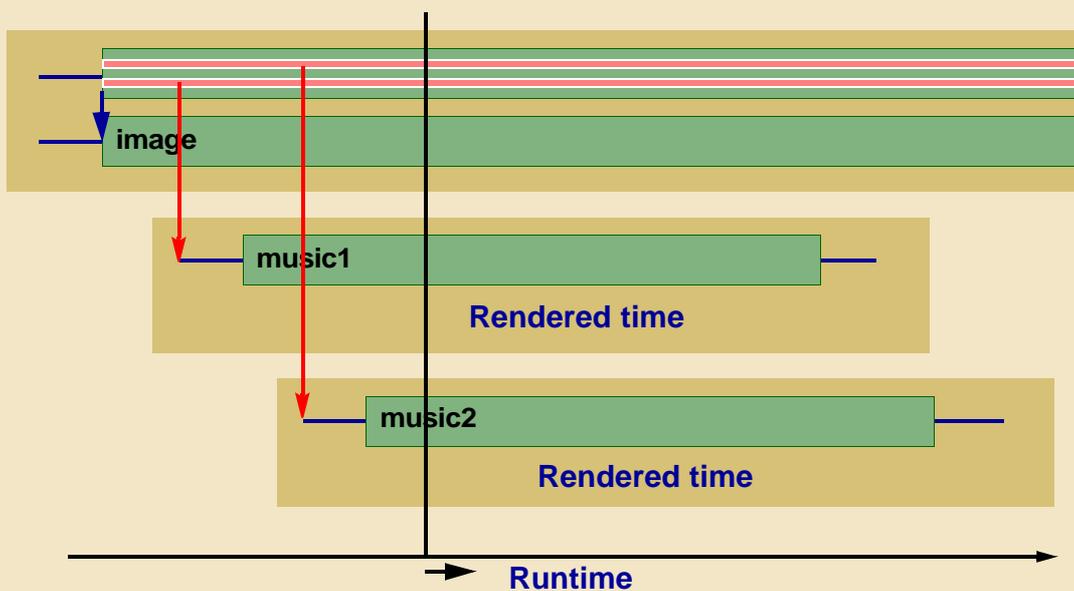

Linking among linear multimedia presentations

Replace

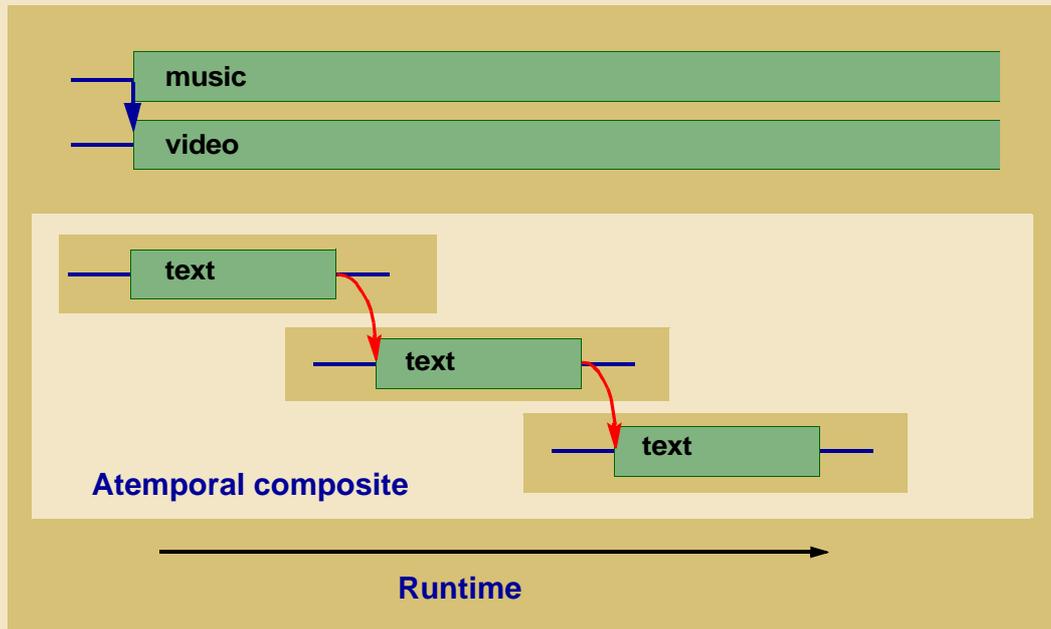

Linking among linear multimedia presentations

Continue

Linking within and among non-linear multimedia presentations

Conclusion

Four types of presentation time

- media element time, document time, rendered time, runtime

Document time needs to be incorporated in document model

Runtime most important from reader's point of view

- traversing time axis
- linking among multimedia presentations
- linking within and among non-linear multimedia presentations

Behaviour has consequences for document model

- temporal and atemporal composition
- link definition
